LETTER CLAIMING RIGHT OF PRIORITY

Honorable Commissioner of
Patents and Trademarks
Washington, D.C. 20231

June 6, 2000

Sir:

Under the provisions of 35 USC 119 and 37 CFR 1.55, the applicant(s) hereby claim(s) the right of priority based on United Kingdom Patent Application No. (s) 9913195.9 filed June 7, 1999.

A certified copy of said United Kingdom Application is attached.

Respectfully submitted,

ANTONELLI, TERRY, STOUT & KRAUS, LLP

Carl I. Brundidge
Registration No. 29,621

INVESTOR IN PEOPLE

The Patent Office
Concept House
Cardiff Road
Newport
South Wales
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation and Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein together with the Statement of inventorship and of right to grant of a Patent (Form 7/77), which was subsequently filed.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely the company to certain additional company law rules.

**Statement of inventorship and of
right to grant of a patent**

1. Your reference	PAT 99414 GB
2. Patent application number (if you know it)	9913195.5
3. Full name of the or of each applicant	NOKIA MOBILE PHONES LIMITED
4. Title of the invention	SECURITY ARCHITECTURE
5. State how the applicant(s) derived the right from the inventor(s) to be granted a patent	BY VIRTUE OF AN ASSIGNMENT DATED 6 JUNE 1999
6. How many, if any, additional Patents Forms 7/77 are attached to this form? (see note (c))	
7.	<p>I/We believe that the person(s) named over the page (and on any extra copies of this form) is/are the inventor(s) of the invention which the above patent application relates to.</p> <p>Signature  Date 8/3/2000</p> <p>PAUL HIGGIN, AGENT FOR THE APPLICANT</p>
8. Name and daytime telephone number of person to contact in the United Kingdom	PAUL HIGGIN 01252 865000

Notes

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there are more than three inventors, please write the names and addresses of the other inventors on the back of another Patents Form 7/77 and attach it to this form.
- d) When an application does not declare any priority, or declares priority from an earlier UK application, you must provide enough copies of this form so that the Patent Office can send one to each inventor who is not an applicant.
- e) Once you have filled in the form you must remember to sign and date it.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Security Architecture

- 5 The present invention relates to the provision of improved security in a device which has services accessible by other devices communicating with the device. It particularly relates to devices which are accessed over a radio interface in accordance with the Bluetooth specification.
- 10 Figure 1 illustrates a network 2 of radio transceiver units, including a master unit 4 and slave units 6, 8 and 10, communicating by transmitting and receiving radio packets. There is only one master in a network. The network operates in a time division duplex fashion. The transceiver units are synchronised to a common time frame determined by the master unit 4. This
- 15 time frame consists of a series of time slots of equal length. Each radio packet transmitted in the network has its start aligned with the start of a slot and a single packet is transmitted in the network at a time. When the master unit is performing point-to-point communication a transmitted radio packet is addressed to a particular transceiver which replies to the master unit by
- 20 transmitting a radio packet addressed to the master unit in the next available time slot. When the master unit is performing point to multi-point communication a transmitted radio packet is addressed to all transceiver units. Any time misalignment between the master and a slave is corrected by adjusting the timing of the slave.
- 25 The transceivers transmit and receive, in this example, in a microwave frequency band, illustratively 2.4 GHz. The network reduces interference by changing the frequency at which each radio packet is transmitted. A number of separate frequency channels are assigned each with a bandwidth of 1MHz,
- 30 and the frequency may hop at a rate of 1600hops/s. The frequency hopping of

the transceivers communicating in or joining the network is synchronised and controlled by the master unit. The sequence of hopping frequencies is unique for the network and is determined by a unique identification of the master unit.

- 5 Each transceiver unit has a unique identification, the Unit ID, henceforth referred to as the Bluetooth ID. Each Bluetooth ID (48-bit IEEE address) is unique for each Bluetooth unit. A Bluetooth ID of a unit can be found through an enquiry routine over the RF interface to the unit.
- 10 The network is a radio frequency network suitable for transmitting voice information or data information between transceivers. The transmissions made are of low power, for example 0 to 20dBm, and the transceiver units can effectively communicate over the range of a few centimetres to a few tens or hundred of metres.
- 15 Referring to Figure 2, a frame 20 is illustrated. This frame 20 is the common time frame used by the network 2 and controlled by the master unit 4. The frame illustratively has slots 22 to 29. The slots designated by even numbers are reserved. Only the master unit can begin transmitting a radio packet aligned with the start of the even numbered slots. The slots designated by odd numbers are reserved. Only radio packets transmitted by a slave, that is radio packets addressed for reception by the master unit can have their start aligned with the start of the odd numbered slots. Each slot is allocated a different one of a sequence of hopping frequencies. It is however, possible for
20 a radio packet to extend over a number of slots and in this case the frequency at which the packet is transmitted remains constant at that allocated to the slot at the start of the packet. A slot has a constant time period and is typically
25 625 microseconds.

Referring to Figure 3, a typical radio packet 30 is illustrated. The radio packet has a start 32 and contains three distinct portions: a first portion contains an Access Code 34, a second portion contains a Header 36 and a third portion contains a Payload 38. The Payload 38 has a Payload Header 37.

5

Referring to Figure 4, a schematic illustration of a transceiver unit is shown. Only as many functional blocks and interconnections are shown in this diagram as are necessary to explain in the following how a transceiver unit and the communication network operates. The transceiver unit 40 contains a number of functional elements including: an antenna 46, receiver 50, synchroniser 52, header decoder 54, controller 60, memory 56, packetiser 42, clock 68, frequency hop controller 48 and transmitter 44. Although these elements are shown as separate elements they may in fact be integrated together and may be carried out in software or in hardware.

15

Data to be transmitted in the payload of a packet by the transceiver unit 40 is supplied as data signal 41 to the packetiser 42. Control information to be transmitted in the payload of a packet is supplied in a payload control signal 87 provided by the controller 60 to the packetiser 42. The packetiser 42 also receives an access code control signal 69 and a header control signal 71 from controller 60 which respectively control the Access Code 34 and the Header 36 attached to the payload to form the packet. The packetiser 42 places the data or control information into a packet 30 which is supplied as signal 43 to the transmitter 44. The transmitter 44 modulates a carrier wave in dependence upon the signal 43 to produce the transmitted signal 45 supplied to the antenna 46 for transmission. The frequency of the carrier wave is controlled to be one of a sequence of hop frequencies by a transmission frequency control signal 47 supplied by the frequency hop controller 48 to the transmitter 44.

30

The antenna 46 receives a radio signal 51 and supplies it to the receiver 50 which demodulates the radio signal 51 under the control of a reception frequency control signal 49 supplied by the frequency controller 48 to produce a digital signal 53. The digital signal 53 is supplied to the synchroniser 52 which synchronises the transceiver unit 40 to the time frame of the network. The synchroniser is supplied with an access code signal 81 specifying the Access Code of the packet which the transceiver unit is expecting to receive. The synchroniser accepts those received radio packets with Access Codes which correspond to the expected Access Codes and rejects those received radio packets with Access Codes that do not correspond to the expected Access Code. A sliding correlation is used to identify the presence and the start of the expected Access Code in a radio packet. If the radio packet is accepted then the radio packet is supplied to the header decoder 54 as signal 55 and a confirmation signal 79 is returned to the controller 60 indicating that the packet has been accepted by the synchroniser 52. The confirmation signal 79 is used by the controller in a slave unit to resynchronise the slave clock to the master clock. The controller compares the time at which a radio packet was received with the time at which the radio packet was expected to be received and shifts its timing to offset the difference. The header decoder 54 decodes the header in the received packet and supplies it to the controller 60 as header signal 75. The header decoder 54, when enabled by a payload acceptance signal 77 supplied by the controller 60, produces a data output signal 57 containing the remainder of the radio packet, the payload 38.

The memory 56 may store applications.

The operation of unit can also be understood from Figure 5 which illustrates a Bluetooth protocol stack 100. The stack 100 includes, in order from the bottom up, the basic layers including RF layer 102, Baseband and Link Control layer 104, Link Manager Protocol Layer 106 and Logical Link Control

and Adaptation Layer (L2CAP)108. The layer L2CAP 108 connects with a number of overlying layers 110 including an Internet layer 112 for providing TCP/IP protocol, a Human Interface Device layer 114 for interfacing with the user interface 130 and a RF Communications layer 116 which emulates serial ports of a PC (com1, com2 com3 etc). Each of the layers 112, 114 and 116 may connect directly with one or more applications/services 118 and are able to multiplex their output so that data is sent to the correct one of several applications/services. The layer L2CAP 108 may also connect directly to an application or service.

10

In the units currently proposed, the Baseband and Link Control layer 104 enables the physical RF link between units using inquiry and paging to synchronise their clocks and transmission frequencies. The Link Manager Protocol Layer 106, henceforth referred to as the Link Layer 106, is responsible for link set-up between two units including security, control of packet size, connection and power modes. In the proposal the Link Layer 106 responds to the payloads received in Link Management Protocol packets.

L2CAP allows higher level protocols to receive the payloads of received L2CAP data packets. The L2CAP protocol may be coupled to application and higher protocol layers and transfers data between either higher level protocols and services and the lower level Link Layer 106.

The payload header 37 of the payload 38 in packets 30 distinguishes L2CAP packets from Link Management Protocol packets. At present, it is required that the Link Management Protocol packets should be filtered out by the Link Layer 106 and not propagated to higher layers.

The Bluetooth technology should provide security measures both at the application layer and the link layer. Currently, in each Bluetooth unit the link

layer 106 security measures are standardised. Authentication and encryption routines are implemented in a standard way in each device in the Link Layer 106.

- 5 Each unit stores one or more secret authentication link keys for use in communication with another unit or units. Typically a unit will permanently store a link key for each of the units it wishes to communicate with. Each link key is associated with the Bluetooth ID of the unit for which it is used to communicate.

10

The stored secret link key is used in an authentication routine to authenticate the identity of the unit being communicated with. The stored shared secret link key is also used to generate an encryption key. The encryption key is derived from but is different to the authentication link key and a new encryption key is generated each time encryption is used by using a random number generator .

15

A challenge response scheme is used to authenticate a unit. A valid pair of units share the same secret link key. A first unit produces a random number and challenges a second unit to authenticate itself by supplying the random number to it. The second unit returns the result of a function which takes as its arguments the Bluetooth ID of the second unit, the received random number and the key associated with the first unit but stored in the second unit. The first unit uses the same function to produce a result which if it equals the result received from the second unit authenticates the second device. The function in the first unit takes as its arguments the Bluetooth ID of the second unit which has been previously obtained, the random number and the key associated with the second unit but stored in the first unit.

20

25

The authentication procedure occurs in the Link Layer of each unit. Once authentication has been successfully completed access to the protocol layer, services and applications in the unit is unrestricted.

- 5 Each time encryption is required a random number is produced and an encryption key is formed from the random number and the authentication key for the link. The encryption process occurs in the Link Layer 106.

- 10 If the two devices have not previously communicated there will be no shared link key stored in the devices and it is necessary to 'pair' the devices. This may be done by inputting a PIN number into a user interface of the first unit and inputting the same PIN into a user interface of the second unit. The PINs may be used for the calculation of temporary initial authentication link keys until the calculation of a permanent shared secret authentication link key for
15 communication between the devices.

- One problem with the presently proposed security system is that it is inflexible. Once the link layer 106 has allowed a device access to the layers above it, its access is unrestricted except by specific security features built
20 into the applications themselves. It would be desirable to provide an improved, more flexible, security system.

- According to one aspect of the present invention there is provide a device as claimed in claim 1.
25

According to another aspect of the present invention there is provided a device as claimed in claim 27.

- According to another aspect of the present invention there is provided a
30 method as claimed in claim 28.

Embodiments of the invention provide a flexible security architecture that performs access checks when connection to a service is requested including, if necessary, authentication and encryption at the time of requesting access to
5 application. The access control means may be a multiplexing protocol layer and the authentication means may be the link layer.

It is preferable that a device requesting access to a service is authenticated once and not many times. This may be achieved by having the request for
10 access to a service arbitrated once-only, preferably in response to a query from the highest possible multiplexing layer (the one that directly interfaces the service).

Access to a service may be arbitrated in dependence on the security
15 requirements of the requested service and/or the trust level of the device requesting access. The security architecture is implemented without changing the basic functions (pairing, authentication, encryption) which remain in the authentication means (link level).

20 According to a further aspect of the present invention there is provided a device as claimed in claim 30.

According to a further aspect of the present invention there is provided a
25 device as claimed in claim 31.

According to embodiments of the invention, access to services depends upon the trust level of the device which is trying to access the service. A trusted device, once its identity has been verified has access to all the services/applications. A not-trusted device may require user authorisation
30 each time it attempts to access a service. Therefore the grant of access of a

not-trusted device to one service does not open up the other services to access. Separate user authorisation is required to access each of the other services.

- 5 For a better understanding of the present invention and to understand how the same may be brought into effect reference will now be made by way of example only to accompanying drawings in which:

Figure 1 illustrates a communications network including a master and slave
10 units;

Figure 2 illustrates the time frame of the communications network;

Figure 3 illustrates a radio packet

Figure 4 illustrates a transceiver unit suitable for use as a master or slave;

Figure 5 illustrates a protocol stack used by a transceiver unit;

- 15 Figure 6 illustrates a security architecture;

Figures 7a and 7b illustrate, respectively, a service database and a device database;

Figures 8a and 8b illustrate information flow in the security architecture when access for a not-open service is requested by a trusted and untrusted device
20 respectively

Figures 9 to 11 are flow diagrams illustrating the arbitration process performed by the controller to determine if a device should access a service.

Figure 6 illustrates a security architecture in accordance with one embodiment
25 of the invention. The Bluetooth protocol stack 100 is illustrated. It includes lower layers including the link layer 106, a lowest multiplexing protocol layer 108 such as the L2CAP layer, a higher multiplexing protocol layer 110 such as the RFCOMM layer 116 and an application layer 118. Also illustrated are the User Interface 130, a security manager 120, a service database 122 and
30 a device database 124.

The link layer 106 is directly connected to the lowest multiplexing protocol 108. Access to the higher multiplexing protocol 110 and the applications/services 118 from the link layer can only be achieved via the
5 lowest multiplexing protocol layer 108.

The lowest multiplexing protocol layer 108 is directly connected to the higher multiplexing protocol 110 and also directly connected to application 118₃. Access to the application 118₃ can be made directly by the lowest multiplexing
10 protocol, whereas access to applications 118₁ and 118₂ can only be made via the higher multiplexing protocol 110 which is directly connected to applications 118₁ and 118₂.

When a packet is received by a unit, the payload of the packet is passed to
15 the lowest multiplexing protocol layer 108. The payload is not filtered by the link layer 106. If the received packet is a request to access a service/application, access to that service application is arbitrated.

The lowest multiplexing protocol layer 108 sends a query to the security
20 manager asking whether access to a higher entity such as the higher protocol layer 110 or application 118₃ should be given. This query identifies the service/application to which access is required and the Bluetooth ID of the device requesting access. The Security Manager determines if access to the next entity should be allowed and may control the Link Layer 106 to enforce
25 authentication. If the querying protocol layer is not directly connected to the requested service, the Security Manager automatically sends a grant signal to the querying protocol layer 108 which then allows access to a higher protocol layer 110. If the querying protocol layer 108 is directly connected to the requested service 118₃, the Security Manager arbitrates to determine if
30 access should be allowed. If access is allowed it sends a grant signal to the

lowest multiplexing protocol layer 108 which then accesses the application 18₃. If access is denied, the Security Manager 120 sends a refusal signal to the lowest multiplexing protocol 108 preventing access of the requesting unit to the desired service.

5

The request to access a service (application 118₁ or 118₂) received at the higher multiplexing protocol 110 from the lowest multiplexing protocol 108, causes the layer 110 to send a query to the Security Manager asking whether access to a higher entity such as a higher multiplexing protocol layer (not illustrated) or application 118₁ or 118₂. This query identifies the service/application to which access is required and the Bluetooth ID of the device requesting access. If the querying protocol layer is not directly connected to the requested service, the Security Manager automatically sends a grant signal to the querying protocol layer 108 which then allows access to a higher protocol layer. If the querying protocol layer 110 is directly connected to the requested service, the Security Manager arbitrates to determine if access should be allowed. If access is allowed it sends a grant signal to the querying protocol layer 110 which then accesses the requested application. If access is denied, the Security Manager 120 sends a refusal signal to the querying protocol layer 110 preventing access of the requesting unit to the desired service.

The lowest multiplexing protocol 108 makes an enquiry to the Security Manager for every received request for access to a service. The request is allowed to progress to a higher layer or service only if access is granted by the Security Manager. Each of the multiplexing protocol layers through which a request to access a service is routed, makes an enquiry to the Security Manager each time a request is received. The request is allowed to progress to a higher layer or service only if access is granted by the Security Manager.

No application/service can therefore be accessed by a unit without at least one arbitration by the Security Manager.

5 The Security manger 120 is a software module with interfaces to protocols 108 and 110, services/applications 118, the UI 130, the databases 122 and 124 and the link layer 106. The security manager controls the link layer and the performance of its standard functions such as authentication, encryption and pairing. The Security Manager knows the identity of the services each of the protocol layers has direct access to.

10 The Security Manager may use its interfaces to the service database 122, the device database, the link manager and the UI 130 to perform an above-mentioned arbitration. An exemplary service database is illustrated in Figure 7a and an exemplary device database is illustrated in Figure 7b. When the
15 Security Manager receives a query from the protocol layers or applications it queries the databases 122 and 124. It accesses the fields associated with the requested application/service from the service database and accesses the fields associated with the Bluetooth ID of the requesting unit from the device database124.

20 The databases are used to define different security levels for devices and services. Each unit has a device database which stores information about other devices it has previously communicated with. The device database has an entry for each Bluetooth ID of the other devices. Each entry has
25 associated fields including a first field to indicate whether that device is trusted or not trusted, a second field for storing the current link key for communication with that devices and a third field to indicate whether there has been a successful authentication with that device in the current session.

The trusted field is binary and there are therefore two security levels for devices- trusted and not-trusted. If a first unit records a second unit as trusted in its device database, then that second unit can access all the services of the first unit after authentication. If the first unit records the second unit as not-trusted (untrusted), the second unit may have its access to the services of the first unit restricted in dependence upon the service database in the first unit.

Each unit has a service database (Figure 7a) which stores information about the applications and services in that unit available for access by another unit. The service database has an entry for each available application or service. Each entry has associated fields including a first field to indicate whether that service is open or not open and a second field to indicate whether encryption is required. This security information can be provided by the services/applications to the security manager during a registration procedure.

The Security Manager defines three levels of security in relation to a service. What the level is depends upon the security rating of the service (open/ not-open) and the security rating of the requesting device (trusted/untrusted). When the security rating of the service is open there is no dependence upon whether the requesting device is trusted or untrusted and the open services are open to all devices.

When the security rating of the service is not-open then there is a dependence upon the trust level of the device requesting access. If the requesting device is trusted, then the device requesting access to the service must be authenticated before access to the service is granted. If the requesting device is untrusted, then the device requesting services must be authenticated and then explicit user authorisation must be given before access to the service is granted.

Referring to the flow diagrams in Figures 9 to 11, after the Security Manager receives an query (200) from the multiplexing protocol layers 108 or 110, it determines whether the querying multiplexing layer is directly connected to (interfaces with) the requested service (201). If the query from the protocol layer concerns a service to which the protocol layer is not directly connected, but is indirectly connected through higher multiplexing protocol layers, the Security Manager allows the passage of the request to the higher multiplexing protocol layer by sending a grant signal to the querying protocol layer. If the query from the querying protocol layer concerns a service to which the querying protocol layer is directly connected, the Security Manager performs an arbitration to determine if access to the service should be allowed or denied.

The arbitration is initiated by the Security Manager accessing (202) the databases 122 and 124, identifying whether the requesting device is trusted and identifying whether the requested service is open (204).

If the requested service is an open service, the Security Manager grants access (216) by sending a grant signal to the querying protocol layer which then accesses the requested application. If the requested service is not an open service the arbitration continues.

If the requesting device is trusted, authentication only is required. If authentication of the requesting device has not occurred in this session (206) (determined from the 3rd field of the entry for the requesting device in the device database), then the security manager instructs the link layer 106 to perform an authentication (208). Referring to Figure 10, the security manager provides the link layer with the current key (if any) stored in the 2nd field of the database entry. The link layer performs the authentication (with pairing if necessary) and informs the security manager if the authentication has been

successful. The processes of pairing (222), checking the link key is current (224) and creating a link key are implementation dependent and are not described further. If the authentication is unsuccessful the Security Manager sends (218) a refusal signal to the querying protocol thereby preventing
5 access to the requested service. If the authentication is successful, link layer also returns the current link key for the requesting device. The Security Manager then updates (210) the device database, placing the current link key in the second field of the database entry and indicating that successful authentication has occurred in this session in the third field of the entry. The
10 Security Manager then determines (212) whether the requesting device is a trusted device. As the device is trusted the Security Manager sends (216) a grant signal to the querying protocol thereby allowing access to the service.

If the requesting device is not-trusted, authentication and user authorisation is
15 required. If authentication of the requesting device has not occurred in this session (206) (determined from the 3rd field of the entry for the requesting device in the device database), then the security manager instructs (208) the link layer 106 to perform an authentication. The security manager provides the link layer with the current key (if any) stored in the 2nd field of the database
20 entry. The link layer performs the authentication (with pairing if necessary) as previously described in relation to Figure 10, and informs the security manager if the authentication has been successful. If the authentication is unsuccessful the Security Manager sends (218) a refusal signal to the querying protocol thereby preventing access to the service. If the
25 authentication is successful the link layer also returns the current link key for the requesting device and the Security Manager updates the device database (210), placing the current link key in the second field of the database entry and indicating that successful authentication has occurred in this session in the third field of the entry. The security manager checks (212) the trusted
30 status of the requesting device. As the device is not-trusted, the security

manager then attempts to obtain user authorisation (214) as illustrated in Figure 11. The security manager controls (230) the UI 130 to indicate to the user that some positive act is required to allow a requesting device access to a service. The service and/or the requesting device may be identified on a screen. The user can agree or disagree to the access. Agreement causes the Security Manager to give (216) a grant signal to the querying protocol layer thereby allowing access to the requested service. Disagreement causes the Security Manager to give (218) a rejection signal to the enquiring protocol thereby preventing access to the requested service. The fact that user authorisation has been given is not recorded and access is therefore one time only. The Security Manager, may then as an option, offer (232) the user the opportunity to change the trust status of the requesting device from untrusted to trusted with subsequent updating (234) of the device database.

If encryption is required in addition to authentication, the Security Manager controls the link layer 106 to perform it, before allowing connection to the application/service requested.

The applications/services 118 and the higher multiplexing protocol 110 must register their multiplexing policies with the Security Manager so that it can determine which application/service is directly connected to each protocol layer.

The process of accessing a service using a trusted device is further illustrated in Figure 8a. The protocol layer is directly connected to a service.

1. Connect request to protocol layer
2. If access control occurs at this protocol layer, then send enquiry to Security Manager
3. Security manager looks up service database
4. Security manager looks up device database

5. Security Manager enforces standard authentication (and possibly encryption) in the link layer
6. Security Manager grants access or link terminated
7. Protocol layer continues to set up the connection by contacting higher protocol layers/ services

The process of accessing a service using an untrusted devices is further illustrated in Figure 8b. The protocol layer is directly connected to a service.

- 1 Connect request to protocol layer
- 10 2 If access control occurs at this protocol layer, then send enquiry to Security Manager
- 3 Security manager looks up service database
- 4 Security manager looks up device database
- 5 Security Manager enforces standard authentication (and possibly encryption) in the link layer
- 15 6 Security Manager asks for manual user authorisation
- 7 Security manager may update device database (trusted?)
- 8 Security Manager grants access or link terminated
- 9 Protocol layer continues to set up the connection by contacting higher protocol layers/services
- 20

In this embodiment authentication (5) is performed before authorisation (6). It would of course be possible to perform authorisation (6) before authentication (5).

- 25 The preceding description describes a preferred implementation of the claimed invention in a preferred application, namely a low power radio frequency communications network in accordance with the Bluetooth Standard. However, it should be appreciated that other implementations and applications may be utilised without departing from the scope of the invention
- 30 as claimed.

In particular, in the embodiment described, whether or not device authentication is required depends simply on the service requested and the content of the service database, in particular, whether the service is open or not-open. Whether or not user authorisation is required is dependent on the service requested and the content of the service database, in particular, whether the service is open or not-open and dependent upon the identity of the device requesting access and the content of the device database, in particular, whether the requesting device is trusted or not-trusted.

It would of course be possible to make device authentication solely or additionally dependent upon the trust status of the device requesting the service. It would also be possible to make user authorisation solely or additionally dependent upon the service requested so that, for example, user authorisation is or is not required for a not-trusted device accessing a particular service in dependence on the stored attributes of the service.

In the above embodiments, the operation of the security architecture has been described in relation to a device requesting access to a service in the 'secure' device. The security architecture may operate in both directions so that information is not sent from the 'secure' device to another device without a decision being made by the security manager. A protocol layer, preferably the highest possible multiplexing protocol layer, and the security manager in combination arbitrate whether the information is sent or not. This arbitration may require authentication and/or authorisation as described above.

Claims

1. A device for communicating with other devices to allow them to access applications, comprising:
- 5 at least a first application;
- authentication means for authenticating a communicating device;
- access control means accessible by a communicating device requesting access to the first application without the communicating device having been authenticated by the authentication means, and arranged to arbitrate whether
- 10 access of the communicating device to the first application is granted or refused wherein if the arbitration requires an authentication of the communicating device, the access control means instructs the authentication means to authenticate the communicating device.
- 15 2. A device as claimed in any preceding claim wherein the access control means is arranged to store security indications in association with accessible applications, wherein the stored security indication associated with the first application is indicative of whether authentication of the communicating device is or is not required during arbitration.
- 20 3. A device as claimed in any preceding claim further comprising a user interface for authorising access to an application during arbitration, the access control means being arranged to store security indications in association with accessible applications, wherein the stored security indication associated with
- 25 the first application is indicative of whether user authorisation of the communicating device is or is not required during arbitration.
4. A device as claimed in claim 2 wherein the stored security indication associated with the first application is indicative of whether authentication of

the communicating device is or is not required during arbitration, in independence of the identity of the communicating device.

5. A device as claimed in claim 3 wherein the access control means is further
5 arranged to store trust indications in association with devices, and wherein the stored security indication associated with the first application is indicative of whether user authorisation of the communicating device is or is not required during arbitration in dependence upon any stored trust indication associated with the communicating device.

10

6. A device as claimed in claim 1 further comprising a user interface for authorising access to an application during arbitration, the access control means being arranged to store trust indications in association with devices, wherein if there is a stored trust indication associated with the communicating
15 device then no user authorisation is required.

20

7. A device as claimed in claim 6 wherein the access control means receives indications originating from communicating device identifying the communicating device.

8. A device as claimed in claim 1 further comprising a user interface for authorising access to an application during arbitration, the access control means being arranged to store trust indications in association with devices and to store security indications in association with accessible applications,
25 wherein if there is a stored trust indication associated with the communicating device then no user authorisation is required and if there is no trust indication associated with the communicating device user authorisation is required in dependence on the stored security indication associated with the requested application.

30

9. A device as claimed in claim 5 or 8 wherein the access control means receives indications originating from the communicating device identifying the communicating device and the application requested.

5 10. A device as claimed in any preceding claim having a device database which stores trust indications of different devices.

11. A device as claimed in any preceding claim having a service database for storing security indications of the accessible applications.

10

12 A device as claimed in any preceding claim wherein authentication comprises secret key exchange between the device and the communicating device.

15 13. A device as claimed in any preceding claim wherein the access control means is an/the interface with the first application.

14. A device as claimed in any preceding claim having a protocol stack comprising a first layer and a second higher layer overlying the first layer, with
20 or without, intermediary layers, wherein the first lower layer is the authentication means and the second higher layer is part of the access control means.

15. A device as claimed in claim 14 wherein the second layer in combination
25 with a security manager is the access control means.

16. A device as claimed in claim 14 or 15 wherein the first layer is the Link Manager Protocol Layer according to the presently proposed Bluetooth specification v0.9 or its equivalent.

17. A device as claimed in claim 14, 15 or 16 wherein the second layer is not the Link Manager Protocol Layer according to the presently proposed Bluetooth specification v0.9 or its equivalent.

5 18. A device as claimed in any preceding claim comprising a plurality of applications and a plurality of access control means where each application has an access control means connected to it.

10 19. A device as claimed in claim 18 wherein the plurality of access control means are arranged in a hierarchy, wherein a first access control means at the lowest level in the hierarchy provides access to at least a second access control means and access to one or both of a third access control means and an application, wherein access to each application is provided via one or more access control means including the first access control means and the
15 application's connected access control means, if different, and wherein any access control means is accessible by a communicating device requesting access to one of its connected applications without the communicating device having been authenticated by the authentication means, and is arranged to arbitrate whether access of the communicating device to the one connected
20 application is granted or refused, the connected access control means instructing the authentication means to authenticate the communicating device if the arbitration requires an authentication of the communicating device.

25 20. A device as claimed in any preceding claim when dependent upon claim 14 wherein the or each access control means includes one of a plurality of different multiplexing protocol layers

30 21. A device as claimed in claim 20 wherein each access control means is the combination of the one multiplexing protocol layer and a security manager

22. A device as claimed in claim 20 or 21 wherein the access control means for a particular application is the highest possible multiplexing protocol layer associated with that particular application.

5

23. A device as claimed in any preceding claim when dependent upon claim 14, wherein a request to access the first application proceeds up through the protocol stack to the access control means.

10 24. A device as claimed in claim 23 when dependent upon claim 21, wherein each multiplexing protocol layer, in the route of the request as it proceeds up through the protocol stack, queries the security manager which, if the requested application is not connected to the querying protocol layer, allows access of the request through the querying protocol layer to a higher
15 multiplexing protocol layer, and, if the requested application is connected to the querying protocol layer, performs an arbitration to grant or refuse access of the communicating device to the requested application.

20 25. A device as claimed in claim 15, 21 or 24 wherein the security manager controls the authentication means.

26. A device as claimed in any preceding claim being portable, having a radio transceiver and a user interface comprising a display and user input means.

25 27. A device for communicating with other devices to allow them to access applications, comprising:
at least first and second applications;
authentication means for authenticating a communicating device;
first access control means accessible by a communicating device requesting
30 access to the first application without the communicating device having been

authenticated by the authentication means, and arranged to arbitrate whether access of the communicating device to the first application is granted or refused wherein if the arbitration requires an authentication of the communicating device, the access control means instructs the authentication means to authenticate the communicating device.

second access control means accessible by a communicating device requesting access to the second application without the communicating device having been authenticated by the authentication means, and arranged to arbitrate whether access of the communicating device to the second application is granted or refused wherein if the arbitration requires an authentication of the communicating device, the access control means instructs the authentication means to authenticate the communicating device, wherein the first access control means is accessible by a communicating device requesting access to the second application without the communicating device having been authenticated by the authentication means, and is arranged to provide the access of the communicating device to the second access means.

28. A method of arbitrating the access of a requesting device to a service provided by a providing device comprising:

sending a request to access the service from the requesting device to the providing device;

receiving the request at the providing device and passing it, without authenticating the requesting device, to an arbitration means interfacing the service;

determining, in the arbitration means, whether to grant or refuse access to the first application by the requesting device, wherein if the determination requires an authentication of the requesting device, the authentication is performed during that determination and not previously.

29. A method as claimed in claim 30 wherein the determination is made on the basis of the identity of service requested and/or the identity of the requesting device.

- 5 30. A device for providing services and allowing access by other devices to the provided services, comprising:

an interface for communicating with the other devices and receiving requests to access a service therefrom;

- 10 arbitration means, for determining whether a requesting device communicating through the interface can access a service it has requested access to, arranged to store trust indications in association with requesting devices and arranged to receive from the interface an indication, originating from the other device, identifying the other device, wherein, if the requesting device has a stored trust indication associated therewith no user authorisation is required and if the requesting device has no stored trust indication associated therewith user authorisation is requirable; and
- 15 a user interface for providing user authorisation.

- 20 31. A device for providing services and allowing access by other devices to the provided services, comprising:

an interface for communicating with the other devices and receiving requests to access a service therefrom;

- 25 arbitration means, for determining whether a requesting device communicating through the interface can access a service it has requested access to, arranged to store trust indications in association with requesting devices and store security indications in association with provided services and arranged to receive from the interface indications, originating from the other device, identifying the other device and the service requested, wherein, if the requesting device has a stored trust indication associated therewith no
- 30 user authorisation is required and if the requesting device has no stored trust

indication associated therewith user authorisation is required in dependence upon the stored security indication associated with the requested service; and a user interface for providing user authorisation.

- 5 32. A device substantially as hereinbefore described with reference to and/or as shown in the accompanying Figures.

33. A method of arbitration substantially as hereinbefore described with reference to and/or as shown in Figures 8a and 8b and/or Figures 9 to 11.
